ABSTRACT

We give an algorithm for computing all roots of polynomials over a univariate power series ring over an exact field \mathbb{K} . More precisely, given a precision d , and a polynomial Q whose coefficients are power series in x , the algorithm computes a representation of all power series $f(x)$ such that $Q(f(x)) = 0 \bmod x^d$. The algorithm works unconditionally, in particular also with multiple roots, where Newton iteration fails. Our main motivation comes from coding theory where instances of this problem arise and multiple roots must be handled.

The cost bound for our algorithm matches the worst-case input and output size $d \deg(Q)$, up to logarithmic factors. This improves upon previous algorithms which were quadratic in at least one of d and $\deg(Q)$. Our algorithm is a refinement of a divide & conquer algorithm by Alekhovich (2005), where the cost of recursive steps is better controlled via the computation of a factor of Q which has a smaller degree while preserving the roots.

KEYWORDS

Polynomial root-finding algorithm; power series; list decoding.

1 INTRODUCTION

In what follows, \mathbb{K} is an exact field, and $\mathbb{K}[[x]][y]$ denotes the set of polynomials in y whose coefficients are power series in x over \mathbb{K} .

Problem and main result. Given a polynomial in $\mathbb{K}[[x]][y]$, we are interested in computing its power series roots to some precision, as defined below.

DEFINITION 1.1. Let $Q \in \mathbb{K}[[x]][y]$ and $d \in \mathbb{Z}_{>0}$. A power series $f \in \mathbb{K}[[x]]$ is called a root of Q to precision d if $Q(f) = 0 \bmod x^d$; the set of all such roots is denoted by $\mathcal{R}(Q, d)$.

Our main problem (Problem 1) asks, given Q and d , to compute a finite representation of $\mathcal{R}(Q, d)$; the fact that such a representation exists is explained below (Theorem 2.8). In all the paper, we count operations in \mathbb{K} at unit cost, and we use the soft-O notation $O^\sim(\cdot)$ to give asymptotic bounds with hidden polylogarithmic factors.

PROBLEM 1.

Input:

- a precision $d \in \mathbb{Z}_{>0}$,
- a polynomial $Q \in \mathbb{K}[[x]][y]$ known at precision d .

Output:

- (finite) list of pairs $(f_i, t_i)_{1 \leq i \leq \ell} \subset \mathbb{K}[[x]] \times \mathbb{Z}_{\geq 0}$ such that $\mathcal{R}(Q, d) = \bigcup_{1 \leq i \leq \ell} (f_i + x^{t_i} \mathbb{K}[[x]])$

An algorithm solving this problem must involve finding roots of polynomials in $\mathbb{K}[y]$. The existence, and complexity, of root-finding algorithms for univariate polynomials over \mathbb{K} depends on the nature of \mathbb{K} . In this paper, we assume that \mathbb{K} is such that we can find roots in \mathbb{K} of a degree n polynomial in $\mathbb{K}[y]$ in time $R_{\mathbb{K}}(n)$, for some function $R_{\mathbb{K}} : \mathbb{Z}_{\geq 0} \rightarrow \mathbb{R}$; the underlying algorithm may be deterministic or randomized. For instance, if $\mathbb{K} = \mathbb{F}_q$, we can take $R_{\mathbb{K}}(n) \in O^\sim(n)$ using either a Las Vegas algorithm (in which case the runtime can be more precisely stated as $O^\sim(n \log(q))$ [19, Cor. 14.16]), or a deterministic one (with for instance a runtime $O(nk^2 \sqrt{p})$, where we write $q = p^k$, p prime [17]).

We now state our main result: we separate the cost of the root-finding part of the algorithm, which may be randomized, and the rest of the algorithm which is deterministic.

THEOREM 1.2. There is an algorithm which solves Problem 1 using $O^\sim(dn)$ deterministic operations in \mathbb{K} , together with an extra $O(dR_{\mathbb{K}}(n))$ operations, where $n = \deg(Q)$.

A cost in $O^\sim(dn)$ is essentially optimal for Problem 1. Indeed, if $Q = (y - f_1) \cdots (y - f_n)$, for some power series f_1, \dots, f_n such that $f_i - f_j$ is a unit for all $i \neq j$, then the roots of Q to precision d are all the power series of the form $f_i + x^d \mathbb{K}[[x]]$, for some i . In this case, solving Problem 1 involves computing all $f_i \bmod x^d$, which amounts to dn elements in \mathbb{K} .

Previous work. When the discriminant of $Q \in \mathbb{K}[[x]][y]$ has x -valuation zero, or equivalently, when all y -roots of $Q|_{x=0}$ are simple (as in the example above), our problem admits an obvious solution: first, compute all y -roots of $Q|_{x=0}$ in \mathbb{K} , say y_1, \dots, y_ℓ , for some $\ell \leq n$, where $n = \deg Q$. Then, apply Newton iteration to each of these roots to lift them to power series roots f_1, \dots, f_ℓ of precision d ; to go from precision say $d/2$ to d , Newton iteration replaces f_i by

$$f_i - \frac{Q(f_i)}{Q'(f_i)} \bmod x^d,$$

where $Q' \in \mathbb{K}[[x]][y]$ is the formal derivative of Q . The bottleneck of this approach is the evaluation of all $Q(f_i)$ and $Q'(f_i)$. Using an algorithm for fast multi-point evaluation in the ring of univariate

polynomials over $\mathbb{K}[\mathbf{x}]/(x^d)$, these evaluations can both be done in $O(dn)$ operations in \mathbb{K} . Taking all steps into account, we obtain the roots f_1, \dots, f_ℓ modulo x^d using $O(dn)$ operations in \mathbb{K} ; this is essentially optimal, as we pointed out above. In this case, the total time for root-finding is $R_{\mathbb{K}}(n)$.

Thus, the non-trivial cases of Problem 1 arise when $Q|_{x=0}$ has multiple roots. In this case, leaving aside the cost of root-finding, which is handled in a non-uniform way in previous work, we are not aware of an algorithm with a cost similar to ours. The best cost bounds known to us are $O(n^2d)$, obtained in [1] and with this cost estimate being showed in [13], and $O(nd^2)$, obtained in [4].

When $Q|_{x=0}$ has multiple roots, a natural generalization of our problem consists in computing Puiseux series solutions of Q . It is then customary to consider a two-stage computation: first, compute sufficiently many terms of the power series / Puiseux series solutions in order to be able to *separate* the branches, then switch to another algorithm to compute many terms efficiently.

Most algorithms for the first stage compute the so-called singular parts of rational Puiseux expansions [7] of the solutions. They are inspired by what we will call the *Newton-Puiseux* algorithm, that is, Newton's algorithmic proof that the field of Puiseux series $\mathbb{K}\langle\langle x \rangle\rangle$ is algebraically closed when \mathbb{K} is algebraically closed of characteristic zero [12, 20]. In the case of Puiseux series roots, one starts by reading off the leading exponent γ of a possible solution on the Newton polygon of the input equation $Q \in \mathbb{K}\langle\langle x \rangle\rangle[y]$. The algorithm then considers $\hat{Q} = Q(x^\gamma y)/x^s \in \mathbb{K}\langle\langle x \rangle\rangle[y]$, where s is the valuation at x of $Q(x^\gamma y)$. If y_1, \dots, y_ℓ are the y -roots of $\hat{Q}|_{x=0}$, then these give the x^γ terms of the Puiseux series roots of Q . For each i we then replace Q with $Q(x^\gamma(y_i + y))/x^{s'}$, where s' is the valuation at x of $Q(x^\gamma(y_i + y))$. This allows us to compute the terms of the solutions one by one. The best algorithms to date [14, 15] use an expected number of $O(n^2v + n^3 + n^2 \log(q))$ operations in \mathbb{K} , if $\mathbb{K} = \mathbb{F}_q$ and where v is the valuation of the discriminant of Q . These algorithms are randomized of the Las Vegas type, since they rely on Las Vegas root-finding in $\mathbb{F}_q[y]$.

In the second stage, given the singular parts of the solutions, it becomes for instance possible to apply Newton iteration, as in [9]. If Q is actually in $\mathbb{K}[x][y]$, one may alternatively derive from it a linear recurrence with polynomial coefficients satisfied by the coefficients of the solutions we are looking for; this allows us to compute them at precision d using $O(dn)$ operations, that is, in time genuinely linear in n, d [5, 6] (keeping in mind that in both cases, we may need to know about v terms of the solutions before being able to switch to the faster algorithm). We will discuss a similar observation in the context of our algorithm, in Section 4.

Using ideas akin to the Newton-Puiseux algorithm, Berthomieu, Lecerf, and Quintin gave in [4] an algorithm that computes roots of polynomials in $L[y]$, for a wide class of local rings L . In the particular case $L = \mathbb{F}_q[[x]]$ with $q = p^s$, the expected runtime of their algorithm is $O(nd^2 + n \log(q) + nd \log(k)/p)$ operations in \mathbb{F}_q .

Let us finally mention algorithms for polynomial factorization over local fields. Using the Montes algorithm [10], it is proved in [3] that one can compute a so-called OM-factorization of a degree n polynomial Q in $\mathbb{F}_q\langle\langle x \rangle\rangle[y]$ at precision d using $O(n^2v + nv^2 + nv \log(q))$, where v is the valuation of the discriminant of Q ; the relation to *basic root sets*, defined below, remains to be elucidated.

Sudan's and Guruswami-Sudan's algorithms for the list-decoding of Reed-Solomon codes [8, 18] have inspired a large body of work, some of which is directly related to Problem 1. These algorithms operate in two stages: the first stage finds a polynomial in $\mathbb{K}[x, y]$ with some constraints; the second one finds its factors of the form $y - f(x)$, for f in $\mathbb{K}[x]$.

The Newton-Puiseux algorithm can easily be adapted to compute such factors; in this context, it becomes essentially what is known as the Roth-Ruckenstein algorithm [16]; its cost is in $O(d^2n^2)$, omitting the work for univariate root-finding.

In the context of Sudan's and Guruswami-Sudan's algorithms, we may actually be able to use Newton iteration directly, by exploiting the fact that we are looking for *polynomial* roots. Instead of computing power series solutions (that is, the Taylor expansions of these polynomial roots at the origin), one can as well start from another expansion point x_0 in \mathbb{K} ; if the discriminant of Q does not vanish at x_0 , Newton iteration applies. If \mathbb{K} is finite, one cannot exclude the possibility that all x_0 in \mathbb{K} are roots of Q ; if needed, one may then look for x_0 in an extension of \mathbb{K} of small degree. Augot and Pecquet showed in [2] that in the cases appearing in Sudan's algorithm, there is always a suitable x_0 in \mathbb{K} .

However, for example for the Wu list decoding algorithm [21] or for the list-decoding of certain algebraic geometry codes [13], one does seek truncated power series roots. In this case, one may use Alekhovich's algorithm [1, App.], which is a divide and conquer variant of the Roth-Ruckenstein algorithm. It solves Problem 1 using $n^{O(1)}O(d)$ operations in \mathbb{K} plus calls to univariate root-finding; the refined analysis in [13] gives the runtime $O(n^2d + nd \log q)$.

Outline. We start by giving properties about the structure of the set of roots in Section 2. We will see in particular how $\mathcal{R}(Q, d)$ can be described recursively as the finite union of set of roots at a lower precision for shifts of Q , that is, polynomials of the form $Q(f + x^t y)$. From this, we will be able to derive a divide-and-conquer algorithm which is essentially Alekhovich's.

The reason why the runtime of this algorithm is quadratic in n is the growth of the (sum of the) degrees of these shifts. Having in mind to control this degree growth, we conclude Section 2 with the definition of so-called *reduced root sets*, for which we establish useful degree properties.

In Section 3, we detail a fast algorithm for the computation of *affine factors*, which are polynomials having the same roots as the shifts but which can be computed more efficiently thanks to the degree properties of our reduced root sets. Finally, in Section 4, we incorporate this into the divide and conquer approach, leading to our fast power series roots algorithm.

2 STRUCTURE OF THE SET OF ROOTS

Recall the notation of Problem 1. In the following analysis, we consider knowing Q to arbitrary precision, i.e. $Q \in \mathbb{K}[[x]][y]$. For convenience, we also define for any $d \leq 0$ that $\mathcal{R}(Q, d) = \mathbb{K}[[x]]$. First, we introduce basic notation.

- $v_x : \mathbb{K}[[x]][y] \setminus \{0\} \rightarrow \mathbb{Z}_{\geq 0}$ denotes the valuation at x , that is, $v_x(Q)$ is the greatest power of x which divides Q , for any nonzero $Q \in \mathbb{K}[[x]][y]$.
- For $Q \in \mathbb{K}[[x]][y]$, we write $Q|_{x=0}$ for the univariate polynomial in $\mathbb{K}[y]$ obtained by replacing x by 0 in Q .

- We denote by $\mathcal{S}_d = \mathbb{K}[[x]]/(x^d)$ the ring of power series in x over \mathbb{K} truncated at precision d .
- To avoid confusion, $\deg(\cdot)$ stands for the degree of some polynomial in y over \mathbb{K} , over $\mathbb{K}[[x]]$, or over \mathcal{S}_d , whereas the degree of polynomials in $\mathbb{K}[x]$ is denoted using $\deg_x(\cdot)$.

The next lemma follows from the above definitions, and shows that we can focus on the case $v_x(Q) = 0$.

LEMMA 2.1. *Let $Q \in \mathbb{K}[[x]][y]$ be nonzero and let $d \in \mathbb{Z}_{>0}$. If $Q|_{x=0} = 0$, then $\mathcal{R}(Q, d) = \mathcal{R}(x^{-s}Q, d - s)$, where $s = v_x(Q)$.*

Now, we will focus on a compact way of representing root sets, and we will see that $\mathcal{R}(Q, d)$ always admit such a representation even though it is usually an infinite set. Similar representations are also behind the correctness and the efficiency of the algorithms of Roth-Ruckenstein [16], of Alekhovich [1, App.], and of Berthomieu-Lecerf-Quintin [4, Sec. 2.2]. To support the divide-and-conquer structure of our algorithm, we further describe how these representations compose.

DEFINITION 2.2. *Let $Q \in \mathbb{K}[[x]][y]$ be nonzero and let $d \in \mathbb{Z}_{>0}$. A basic root set of Q to precision d is a finite set of pairs $(f_i, t_i)_{1 \leq i \leq \ell}$, each in $\mathbb{K}[x] \times \mathbb{Z}_{\geq 0}$, such that:*

- $v_x(Q(f_i + x^{t_i}y)) \geq d$ for $1 \leq i \leq \ell$,
- we have the identity

$$\mathcal{R}(Q, d) = \bigcup_{1 \leq i \leq \ell} \{f_i + x^{t_i} \mathbb{K}[[x]]\}.$$

For $d \leq 0$, we define the unique basic root set of Q to precision d as being $\{(0, 0)\}$; note that it satisfies both conditions above.

We remark that the first restriction on being a basic root set is key: for instance, $Q = y^2 + y \in \mathbb{F}_2[[x]][y]$ has $\mathcal{R}(Q, 1) = \mathbb{F}_2[[x]]$. But $\{(0, 0)\}$ is not a basic root set because it does not satisfy the first property; rather a basic root set is given by expanding the first coefficient: $\{(0, 1), (1, 1)\}$.

At precision $d = 1$, one can easily build a basic root set of Q which has small cardinality:

LEMMA 2.3. *Let $Q \in \mathbb{K}[[x]][y]$ be such that $Q|_{x=0} \neq 0$, and let y_1, \dots, y_ℓ be the roots of $Q|_{x=0}$. Then, $(y_i, 1)_{1 \leq i \leq \ell}$ is a basic root set of Q to precision 1.*

PROOF. Take i in $\{1, \dots, \ell\}$ and write the Taylor expansion of $Q(y_i + xy)$ as $Q(y_i + xy) = Q(y_i) + xR_i(y)$, for some $R_i \in \mathbb{K}[[x]][y]$. Since both terms in the sum have valuation at least 1, we obtain that $s_i = v_x(Q(y_i + xy))$ is at least 1. Furthermore, we remark that

$$\begin{aligned} \mathcal{R}(Q, 1) &= \{f \in \mathbb{K}[[x]] \mid Q(f) = 0 \bmod x\} \\ &= \{f \in \mathbb{K}[[x]] \mid Q|_{x=0}(f_0) = 0\}, \end{aligned}$$

where f_0 is the constant coefficient of f . Thus, $\mathcal{R}(Q, 1)$ is the set of $f \in \mathbb{K}[[x]]$ whose constant coefficient is in $\{y_1, \dots, y_\ell\}$. \square

PROPOSITION 2.4. *Let $Q \in \mathbb{K}[[x]][y]$ be such that $Q|_{x=0} \neq 0$ and let d', d be in $\mathbb{Z}_{\geq 0}$, with $d' \leq d$. Suppose that Q admits a basic root set $(f_i, t_i)_{1 \leq i \leq \ell}$ to precision d' . Suppose furthermore that, for $1 \leq i \leq \ell$, $Q(f_i + x^{t_i}y)/x^{s_i}$ admits a basic root set $(f_{i,j}, t_{i,j})_{1 \leq j \leq \ell_i}$ to precision $d - s_i$, where $s_i = v_x(Q(f_i + x^{t_i}y))$. Then, a basic root set of Q to precision d is given by*

$$(f_i + f_{i,j}x^{t_i}, t_i + t_{i,j})_{1 \leq j \leq \ell_i, 1 \leq i \leq \ell}.$$

PROOF. For $1 \leq i \leq \ell$, let $Q_i = Q(f_i + x^{t_i}y)/x^{s_i}$. Then, for all i, j , from the definition of basic root sets, we have

$$\begin{aligned} v_x(Q(f_i + f_{i,j}x^{t_i} + x^{t_i+t_{i,j}}y)) &= v_x(x^{s_i}Q_i)|_{y=f_{i,j}+x^{t_{i,j}}y} \\ &\geq s_i + (d - s_i). \end{aligned}$$

This proves that the first property of Definition 2.2 holds.

For the second property, we prove both inclusions leading to the identity $\mathcal{R}(Q, d) = \bigcup_{i,j} \{f_i + x^{t_i}f_{i,j} + x^{t_i+t_{i,j}}\mathbb{K}[[x]]\}$.

First, consider some $f \in \mathcal{R}(Q, d)$; since $d' \leq d$, f is in $\mathcal{R}(Q, d')$, so we can write $f = f_i + x^{t_i}g$, for some i in $\{1, \dots, \ell\}$ and g in $\mathbb{K}[[x]]$. Then, $Q(f) = x^{s_i}Q_i(g) = 0 \bmod x^d$, and so $g \in \mathcal{R}(Q_i, d - s_i)$. This implies that $g \in f_{i,j} + x^{t_{i,j}}\mathbb{K}[[x]]$ for some j .

Now consider a power series $g \in \mathcal{R}(Q_i, d - s_i)$ for some i . This means that $Q_i(g) = 0 \bmod x^{\max(0, d-s_i)}$, so that $Q(f_i + x^{t_i}g) = x^{s_i}Q_i(g) = 0 \bmod x^d$, and therefore $f_i + x^{t_i}g$ is in $\mathcal{R}(Q, d)$. \square

We now deduce, by induction on d , that any $Q \in \mathbb{K}[[x]][y]$ admits a finite basic root set to precision d for any $d \in \mathbb{Z}_{\geq 0}$. By Lemma 2.1 we can reduce to the case where $v_x(Q) = 0$ and $Q|_{x=0} \neq 0$. The claim is readily seen to be true for $d \leq 0$ (take $\{(0, 0)\}$) and $d = 1$ (Lemma 2.3). Suppose the claim holds for all $d' < d$, for some $d \geq 2$; we can then apply this property to $d - 1$, obtaining a basic root set $(f_i, t_i)_{1 \leq i \leq \ell}$ of Q to precision $d - 1$. We know that, with the notation of Proposition 2.4, $s_i \geq d - 1$ holds for all i , so in particular $s_i \geq 1$, and thus $d - s_i < d$. Then, applying again the induction property to each $(Q_i, d - s_i)_i$, the conclusion of Proposition 2.4 establishes our claim.

These results can be used to build basic root sets recursively, by either applying Lemma 2.3 iteratively or using Proposition 2.4 in a divide-and-conquer fashion with Lemma 2.3 applied at the leaves. As discussed in Section 1, this recursive approach is similar to the Newton-Puiseux algorithm. These iterative and divide and conquer solutions to Problem 1 are known in coding theory as the Roth-Ruckenstein algorithm [16] and the Alekhovich algorithm [1, App.]. Below, we describe the latter algorithm in detail (Algorithm 1), since our new algorithm runs along the same lines (Algorithm 4). We will not further discuss the correctness or complexity of Algorithm 1, but rather refer to [1, App.] or [13, App. A].

Algorithm 1 : DnCSeriesRoots [1]

Input: $d \in \mathbb{Z}_{>0}$ and $Q \in \mathcal{S}_d[y]$ with $Q|_{x=0} \neq 0$.

Output: A basic root set of Q to precision d .

```

1 if  $d = 1$  then
2    $(y_i)_{1 \leq i \leq \ell} \leftarrow$  roots of  $Q|_{x=0} \in \mathbb{K}[y]$ 
3   return  $(y_i, 1)_{1 \leq i \leq \ell}$ 
4 else
5    $(f_i, t_i)_{1 \leq i \leq \ell} \leftarrow \text{DnCSeriesRoots}(Q \bmod x^{\lceil d/2 \rceil}, \lceil d/2 \rceil)$ 
6    $(Q_i)_{1 \leq i \leq \ell} \leftarrow (Q(f_i + x^{t_i}y) \bmod x^d)_{1 \leq i \leq \ell}$ 
7    $(s_i)_{1 \leq i \leq \ell} \leftarrow (v_x(Q_i))_{1 \leq i \leq \ell}$ 
8   for  $1 \leq i \leq \ell$  do
9     if  $s_i \geq d$  then
10       $(f_{i,1}, t_{i,1}) \leftarrow (0, 0)$  and  $\ell_i \leftarrow 1$ 
11    else
12       $(f_{i,j}, t_{i,j})_{1 \leq j \leq \ell_i} \leftarrow \text{DnCSeriesRoots}(x^{-s_i}Q_i, d - s_i)$ 
13  return  $(f_i + x^{t_i}f_{i,j}, t_i + t_{i,j})_{1 \leq j \leq \ell_i, 1 \leq i \leq \ell}$ 

```

The next step is to prove that there are special, small basic root sets, and that these also compose in a way similar to Proposition 2.4. In order to formulate this, we first introduce a generalization of root multiplicity to our setting.

DEFINITION 2.5. Let $(f, t) \in \mathbb{K}[x] \times \mathbb{Z}_{>0}$ be such that f is nonzero and $f = g + f_{t-1}x^{t-1}$ for some $g \in \mathbb{K}[x]$ with $\deg_x(g) < t-1$. For $Q \in \mathbb{K}[x][y] \setminus \{0\}$, we consider the polynomial of valuation zero

$$R = Q(g + x^{t-1}y)/x^{v_x(Q(g+x^{t-1}y))} \in \mathbb{K}[x][y].$$

Then, the root multiplicity of (f, t) in Q is the root multiplicity of f_{t-1} in $R|_{x=0} \in \mathbb{K}[y]$.

Note that if f_{t-1} is not a root of $R|_{x=0}$, the root multiplicity of (f, t) is 0. Also, if $t = 1$, so that $f = f_0$ is in \mathbb{K} , and if $Q|_{x=0} \neq 0$, the root multiplicity of $(f_0, 1)$ is simply the multiplicity of f_0 in $Q|_{x=0}$.

DEFINITION 2.6. Let $Q \in \mathbb{K}[x][y]$ be such that $Q|_{x=0} \neq 0$ and let d be in \mathbb{Z} . Suppose that $(f_i, t_i)_{1 \leq i \leq \ell}$ is a basic root set of Q at precision d . Then, we say that $(f_i, t_i)_{1 \leq i \leq \ell}$ is a reduced root set, if the following holds:

- either $d \leq 0$,
- or $d > 0$, and all the f_i 's are nonzero, and the following points are all satisfied, where for $1 \leq i \leq \ell$, we write $s_i = v_x(Q(f_i + x^{t_i}y))$, $Q_i = Q(f_i + x^{t_i}y)/x^{s_i}$, and we write m_i for the root multiplicity of (f_i, t_i) in Q :
 - (1) $m_i \geq 1$ for $1 \leq i \leq \ell$,
 - (2) $\deg(Q_i|_{x=0}) \leq m_i$ for $1 \leq i \leq \ell$, and
 - (3) $\sum_{1 \leq i \leq \ell} m_i \leq \deg(Q|_{x=0})$.

It follows from the restrictions (1) and (3) that $\ell \leq \deg(Q|_{x=0})$. Mimicking the structure of the first half of the section, we now prove the existence of reduced root sets for $d = 1$ and then give a composition property. The next lemma is inspired by [1, Lem. 1.1].

LEMMA 2.7. Let $Q \in \mathbb{K}[x][y]$ be such that $Q|_{x=0} \neq 0$. The basic root set of Q to precision 1 defined in Lemma 2.3 is reduced.

PROOF. Let y_1, \dots, y_ℓ be the roots of $Q|_{x=0}$, and, for $1 \leq i \leq \ell$, let $s_i = v_x(Q(y_i + xy))$, $Q_i = Q(y_i + xy)/x^{s_i}$, and let m_i be the root multiplicity of y_i in $Q|_{x=0}$.

The inequalities $m_i \geq 1$, for $1 \leq i \leq \ell$, and $\sum_i m_i \leq \deg(Q|_{x=0})$ are clear. Consider now a fixed index i ; it remains to prove that $\deg(Q_i|_{x=0}) \leq m_i$. There are $P \in \mathbb{K}[y]$ and $R \in \mathbb{K}[x][y]$ such that $P(y_i) \neq 0$ and $Q = (y - y_i)^{m_i}P(y) + xR$. Then

$$x^{s_i}Q_i = Q(y_i + xy) = (xy)^{m_i}P(y_i + xy) + xR(y_i + xy).$$

The right-hand side reveals the following:

- Any monomial $x^\alpha y^\beta$ in $x^{s_i}Q_i$ satisfies $\alpha \geq \beta$, and hence $\deg(Q_i|_{x=0}) \leq s_i$.
- $x^{s_i}Q_i$ contains the term $(xy)^{m_i}P(y_i)$, since this appears in $(xy)^{m_i}P(y_i + xy)$ and it cannot be cancelled by a term in $xR(y_i + xy)$ since all monomials there have greater x -degree than y -degree.

These two points imply $\deg(Q_i|_{x=0}) \leq s_i \leq m_i$. \square

The following theorem is exactly the statement of Proposition 2.4 except that “basic” has been replaced by “reduced”.

THEOREM 2.8. Let $Q \in \mathbb{K}[x][y]$ be such that $Q|_{x=0} \neq 0$ and let d', d be in $\mathbb{Z}_{\geq 0}$, with $d' \leq d$. Suppose that Q admits a reduced root set $(f_i, t_i)_{1 \leq i \leq \ell}$ to precision d' . For $i = 1, \dots, \ell$, suppose furthermore that $Q(f_i + x^{t_i}y)/x^{s_i}$ admits a reduced root set $(f_{i,j}, t_{i,j})_{1 \leq j \leq \ell_i}$ to precision $d - s_i$, where $s_i = v_x(Q(f_i + x^{t_i}y))$. Then a reduced root set of Q to precision d is given by

$$(f_i + f_{i,j}x^{t_i}, t_i + t_{i,j})_{1 \leq j \leq \ell_i, 1 \leq i \leq \ell}.$$

PROOF. By Proposition 2.4 it is clear that the specified set is a basic root set, and we should verify the additional restrictions of Definition 2.6. Introduce for each i, j

$$Q_{i,j} = Q(f_i + f_{i,j}x^{t_i} + x^{t_i+t_{i,j}}y)/x^{s_{i,j}} = Q_i(f_{i,j} + x^{t_{i,j}}y)/x^{s_{i,j}},$$

where $Q_i = Q(f_i + x^{t_i}y)/x^{s_i}$ and $s_{i,j} = v_x(Q_i(f_{i,j} + x^{t_{i,j}}y))$.

Consider first for some i the case $d - s_i \leq 0$. Then $\ell_i = 1$ and $(f_{i,1}, t_{i,1}) = (0, 0)$, and so the root multiplicity $m_{i,1}$ of $(f_i + f_{i,1}x^{t_i}, t_i + t_{i,1})$ in Q is m_i which is positive by assumption. Also $Q_{i,j} = Q_i$ so $\deg(Q_{i,j}|_{x=0}) = \deg(Q_i|_{x=0})$ which is at most $m_i = m_{i,1}$ by assumption. Finally, $\sum_j m_{i,j} = m_{i,1} = m_i$. We will collect the latter fact momentarily to prove the third item of the reduced root definition.

Consider next an i where $d - s_i > 0$. In this case $t_{i,j} > 0$ for all $1 \leq j \leq \ell_i$, and the root multiplicity of $(f_i + f_{i,j}x^{t_i}, t_i + t_{i,j})$ in Q equals the root multiplicity $m_{i,j}$ of $(f_{i,j}, t_{i,j})$ in Q_i which is positive by assumption. The assumptions also ensure that $\deg(Q_{i,j}|_{x=0}) \leq m_{i,j}$, and $\sum_j m_{i,j} \leq \deg(Q_i|_{x=0}) \leq m_i$.

Thus, the two first restrictions on being a reduced root set is satisfied for each element. All that remains is the third restriction: but using our previous observations, we have $\sum_i \sum_j m_{i,j} \leq \sum_i m_i$ and this is at most $\deg(Q|_{x=0})$ by assumption. \square

To solve Problem 1 we will compute a reduced root set using Lemma 2.7 and Theorem 2.8. Note that it follows that a reduced root set is essentially unique: apart from possible redundant elements among the f_i , non-uniqueness would only be due to unnecessarily expanding a coefficient in a root (f, t) , that is, replace that root by the $|\mathbb{K}|$ roots $(f + ax^t, t + 1)_{a \in \mathbb{K}}$. Of course this could only be an issue if \mathbb{K} is finite and if $\deg(Q|_{x=0})$ is very large. Our algorithm as well as previous ones are computing the “minimal” set of reduced roots. According to Theorem 2.8, the total number of field elements required to represent this minimal set cannot exceed $d \deg(Q|_{x=0}) \leq d \deg(Q)$.

3 AFFINE FACTORS OF THE SHIFTS

The appendix A of [13] gives a careful complexity analysis of Algorithm 1, and proves that it runs in time $O(dn^2 + dnR_{\mathbb{K}})$, where $n = \deg(Q)$. The main reason why the cost is quadratic in $\deg(Q)$ is that all the shifted polynomials $Q_i = x^{-s_i}Q(f_i + x^{t_i}y)$ can have large degree, namely up to $\deg(Q)$. Thus, merely representing the Q_i 's may use a number of field elements quadratic in $\deg(Q)$.

Nonetheless, we are actually not interested in these shifts themselves, but only in their reduced root sets. The number of these roots is well controlled: the shifts have altogether a reduced root set of at most $\deg(Q|_{x=0})$ elements. Indeed, by definition, we know that $\deg(Q_i|_{x=0})$ is at most the multiplicity m_i of the root (f_i, t_i) , and the sum of these multiplicities is at most $\deg(Q|_{x=0})$.

The difficulty we face now is that we want to efficiently compute reduced root sets of the shifts without fully computing these shifts. To achieve this, we compute for each shift Q_i a factor of it which has the same roots and whose degree is $\deg(Q_i|_{x=0}) \leq m_i$, *without entirely computing Q_i itself*. We design a fast algorithm for computing these factors, by using ideas from [11, Algo. Q], in which we also incorporate fast modular reduction techniques so as to carefully control the quantity of information we process concerning the shifts.

The next result formalizes the factorization we will rely on. It is a direct consequence of the Weierstrass preparation theorem for multivariate power series [22, VII.§1. Cor. 1 of Thm. 5].

THEOREM 3.1. *Let $Q \in \mathbb{K}[[x]][y]$ be such that $Q|_{x=0} \neq 0$. Then, there exist unique $A, B \in \mathbb{K}[[x]][y]$ such that $Q = AB$, A is monic and $B|_{x=0} \in \mathbb{K} \setminus \{0\}$.*

In the case at hand, one may as well derive existence and uniqueness of A and B (together with a slow algorithm to compute them) by writing their unknown coefficients as $A = a_0(y) + xa_1(y) + \dots$ $B = b_0 + xb_1(y) + \dots$, with b_0 in $\mathbb{K} \setminus \{0\}$ and all a_i 's ($i \geq 1$) of degree less than that of a_0 . Extracting coefficients of x^0, x^1, \dots , we deduce that the relation $Q = AB$ defines the a_i 's and b_i 's uniquely.

In what follows, A is called the *affine factor* of Q . Remark that if we start from Q in $\mathcal{S}_d[y]$, we can still define its affine factor as a polynomial in $\mathcal{S}_d[y]$, by reducing modulo x^d the affine factor of an arbitrary lift of Q to $\mathbb{K}[[x]][y]$ (the construction above shows that the result is independent of the lift).

Our algorithm will compute the affine factors $(A_i)_{1 \leq i \leq \ell}$ of the shifts $(Q_i)_{1 \leq i \leq \ell}$ at some prescribed precision d in x , having as input Q and the shifting elements $(f_i + x^{t_i}y)_{1 \leq i \leq \ell}$. A factorization $Q_i = A_i B_i$ can be computed modulo any power x^d of x from the knowledge of Q_i by means of Hensel lifting [11, Algo. Q], doubling the precision at each iteration. However, the above-mentioned degree bounds indicate that neither the shifts $(Q_i)_i$ nor the cofactors $(B_i)_i$ may be computed modulo x^d in time quasi-linear in $\deg(Q)$ and d : the key of our algorithm is to show how to compute the affine factors A_i at precision d directly from Q within the prescribed time bounds. (Hensel lifting factorization techniques were also used in [4], but in a context without the degree constraints that prevent us from computing the shifts Q_i). Hereafter, $A \text{ quo } B$ and $A \text{ rem } B$ denote the quotient and the remainder in the division of the polynomial A by the monic polynomial B .

The input of the algorithm is the polynomial Q known modulo x^d , as output, we compute the affine factors A_i of the shifts at respective precisions $d - s_i$, together with the valuation s_i ; if $s_i \geq d$, we detect it and return $(0, d)$. The initialization consists in computing the affine factors of the x -constant polynomials $(Q_i|_{x=0})_{1 \leq i \leq \ell}$. If these polynomials are known, this is straightforward: the affine factor of $Q_i|_{x=0}$ is itself divided by its leading coefficient, which is a nonzero constant from \mathbb{K} . It turns out that computing these polynomials is not an issue; remark that the sum of their degrees is at most $m_1 + \dots + m_\ell \leq \deg(Q)$. Explicitly, we first compute the remainders $(Q(f_i + x^{t_i}y) \text{ rem } y^{m_i+1})_i$ via fast modular reduction techniques; then, we can both retrieve the valuations $(s_i)_i = (v_x(Q(f_i + x^{t_i}y)))_i$ (or, more precisely, $s_i^* = \min(s_i, d)$), and, when $s_i < d$, the x -constant terms of $Q_i = x^{-s_i}Q(f_i + x^{t_i}y)$ to carry out the initialization step (Line 1 to Line 11 in Algorithm 3).

Before continuing to describe the algorithm, we detail one of its main building blocks (Algorithm 2): the fast computation of simultaneous shifted remainders via multiple modular reduction.

Algorithm 2 : ShiftedRem

Input: a commutative ring \mathcal{A} , a polynomial $Q \in \mathcal{A}[y]$, and triples $(A_i, f_i, r_i)_{1 \leq i \leq \ell} \in \mathcal{A}[y] \times \mathcal{A} \times \mathcal{A}$, with the A_i 's monic.

Output: the remainders $Q(f_i + r_i y) \text{ rem } A_i$ for $1 \leq i \leq \ell$.

```

1  $(\tilde{A}_i)_{1 \leq i \leq \ell} \leftarrow (\sum_{0 \leq j \leq \delta_i} r_i^{\delta_i-j} a_{i,j} y^j)_{1 \leq i \leq \ell}$ 
2   where  $(A_i)_{1 \leq i \leq \ell} = (\sum_{0 \leq j \leq \delta_i} a_{i,j} y^j)_{1 \leq i \leq \ell}$  with  $a_{i,\delta_i} = 1$ 
3  $(\hat{A}_i)_{1 \leq i \leq \ell} \leftarrow (\tilde{A}_i(y - f_i))_{1 \leq i \leq \ell}$ 
4  $(\hat{R}_i)_{1 \leq i \leq \ell} \leftarrow (Q \text{ rem } \hat{A}_i)_{1 \leq i \leq \ell}$ 
5  $(R_i)_{1 \leq i \leq \ell} \leftarrow (\hat{R}_i(f_i + r_i y))_{1 \leq i \leq \ell}$ 
6 return  $(R_i)_{1 \leq i \leq \ell}$ 
```

PROPOSITION 3.2. *Algorithm 2 is correct and uses*

$$O(\deg(Q) + \deg(A_1 \cdots A_\ell))$$

operations in \mathcal{A} .

PROOF. Let $i \in \{1, \dots, \ell\}$. Since \hat{A}_i is monic, the remainder $\hat{R}_i = Q \text{ rem } \hat{A}_i$ is well-defined, and $Q = P_i \hat{A}_i + \hat{R}_i$ with $\deg(\hat{R}_i) < \deg(\hat{A}_i)$ and $P_i \in \mathcal{A}[y]$. Then, we have

$$\begin{aligned}
Q(f_i + r_i y) &= P_i(f_i + r_i y) \hat{A}_i(f_i + r_i y) + \hat{R}_i(f_i + r_i y) \\
&= P_i(f_i + r_i y) \tilde{A}_i(r_i y) + R_i(y) \\
&= P_i(f_i + r_i y) r_i^{\delta_i} A_i(y) + R_i(y),
\end{aligned}$$

which ensures $R_i = Q(f_i + r_i y) \text{ rem } A_i(y)$, hence the correctness.

Concerning the cost bound, the polynomial \tilde{A}_i is computed using at most $2\delta_i$ multiplications in \mathcal{A} , where $\delta_i = \deg(A_i)$, and then \hat{A}_i is computed by fast shifting using $O(\delta_i)$ operations in \mathcal{A} [19, Thm. 9.15]. The conclusion follows, since fast remaindering can be used to compute all remainders $(\hat{R}_1, \dots, \hat{R}_\ell)$ simultaneously in $O(\deg(Q) + \delta_1 + \dots + \delta_\ell)$ operations in \mathcal{A} . Indeed, we start by computing the subproduct tree in $O(\delta_1 + \dots + \delta_\ell)$ operations [19, Lem. 10.4], which gives us in particular the product $\hat{A}_1 \cdots \hat{A}_\ell$. Then, we compute the remainder $\hat{R} = Q \text{ rem } \hat{A}_1 \cdots \hat{A}_\ell$, which can be done in $O(\deg(Q) + \delta_1 + \dots + \delta_\ell)$ operations in \mathcal{A} using fast division [19, Thm. 9.6]. Finally, the sought $\hat{R}_i = \hat{R} \text{ rem } \hat{A}_i$ are computed by going down the subproduct tree, which costs $O(\delta_1 + \dots + \delta_\ell)$ operations in \mathcal{A} [19, Cor. 10.17]. \square

Now, let us describe how we implement the Hensel lifting strategy to manage to compute the sought affine factors without fully computing the shifts. In addition to the affine factors, we will make use of partial information on the inverse of the cofactor: we compute this inverse modulo the affine factor. Let $1 \leq i \leq \ell$ and assume that we have computed, at precision K ,

- the affine factor $A_i \in \mathcal{S}_K[y]$ of $Q_i \text{ mod } x^K$,
- $C_i = B_i^{-1} \text{ rem } A_i \in \mathcal{S}_K[y]$, where $B_i \in \mathcal{S}_K[y]$ denotes the cofactor such that $A_i B_i = Q_i \text{ mod } x^K$.

Note that B_i is invertible as a polynomial of $\mathcal{S}_K[y]$ since by definition $B_i|_{x=0} \in \mathbb{K} \setminus \{0\}$. Thus, our requirement is that the inverse of B_i coincides with C_i when working modulo A_i .

Algorithm 3 : AffineFacOfShifts

Input: a precision $d \in \mathbb{Z}_{>0}$, a polynomial $Q \in \mathcal{S}_d[y]$ such that $Q|_{x=0} \neq 0$, and triples $(f_i, t_i, m_i)_{1 \leq i \leq \ell} \subset \mathcal{S}_d \times \mathbb{Z}_{>0} \times \mathbb{Z}_{>0}$.

Output: $(A_i, s_i)_{1 \leq i \leq \ell}$ with $(A_i, s_i) = (0, d)$ if $Q(f_i + x^{t_i}y) = 0$ in $\mathcal{S}_d[y]$, and otherwise $s_i = v_x(Q(f_i + x^{t_i}y)) < d$ and $A_i \in \mathcal{S}_{d-s_i}[y]$ is the affine factor of $Q_i = x^{-s_i}Q(f_i + x^{t_i}y)$ at precision $d - s_i$.

Requires: m_i is such that $A_i = 0$ or $\deg(A_i) \leq m_i$, for $1 \leq i \leq \ell$.

```

1   $\mathcal{I} \leftarrow (1, \dots, \ell)$  /* list of not yet computed factors */
2   $(R_i)_{1 \leq i \leq \ell} \leftarrow \text{ShiftedRem}(\mathcal{S}_d, Q, (y^{m_i+1}, f_i, x^{t_i})_{1 \leq i \leq \ell})$ 
3  /* Process trivial affine factors */
4  for  $1 \leq i \leq \ell$  such that  $R_i = 0$  do
5     $(A_i, s_i) \leftarrow (0, d)$ , and remove  $i$  from  $\mathcal{I}$ 
6  /* Set valuations and compute affine factors mod  $x^4$  */

14    for  $i \in \mathcal{I}$  such that  $d - s_i \leq 2^{k-1}$  do
15      remove  $i$  from  $\mathcal{I}$ 
16       $K \leftarrow 2^{k-1}$ ;  $(\delta_i)_{i \in \mathcal{I}} \leftarrow (\min(K, d - s_i - K))_{i \in \mathcal{I}}$ 
17      /* Lift the affine factors  $(A_i)_i$  to precisions  $\delta_i + K$  */
18       $(R_i)_{i \in \mathcal{I}} \leftarrow \text{ShiftedRem}(\mathcal{S}_d, Q, (\tilde{A}_i, f_i, x^{t_i})_{i \in \mathcal{I}})$ ,
19      where  $\tilde{A}_i$  is  $A_i$  lifted into  $\mathcal{S}_d[y]$ 
20       $(A_{i\top} \in \mathcal{S}_{\delta_i}[y])_{i \in \mathcal{I}} \leftarrow ((x^{-s_i-K}R_iC_i) \text{ rem } A_i)_{i \in \mathcal{I}}$ ,
21      with  $x^{-s_i-K}R_i, C_i$ , and  $A_i$  truncated at precision  $\delta_i$ 
22       $(A_i \in \mathcal{S}_{\delta_i+K}[y])_{i \in \mathcal{I}} \leftarrow (A_i + x^K A_{i\top})_{i \in \mathcal{I}}$ 
23      /* Find the cofactor inverses  $(C_i)_i$  at precisions  $\delta_i + K$  */
24       $(S_i)_{i \in \mathcal{I}} \leftarrow \text{ShiftedRem}(\mathcal{S}_d, Q, (\tilde{A}_i^2, f_i, x^{t_i})_{i \in \mathcal{I}})$ ,
25      where  $\tilde{A}_i$  is  $A_i$  lifted into  $\mathcal{S}_d[y]$ 
26       $(C_i \in \mathcal{S}_{\delta_i+K}[y])_{i \in \mathcal{I}} \leftarrow (((x^{-s_i}S_i) \text{ quo } A_i)^{-1} \text{ rem } A_i)_{i \in \mathcal{I}}$ ,
27      with  $x^{-s_i}S_i$  and  $A_i$  truncated at precision  $\delta_i + K$ 
28  return  $(A_i, s_i)_{1 \leq i \leq \ell}$ 

```

Now, we want to find similar polynomials when we increase the precision to $2K$. The main point concerning efficiency is that we will be able to do this by only considering computations modulo the affine factors A_i and their squares; remember that we control the sum of their degrees. In the algorithm, we increase for each i the precision from K to $K + \delta_i$, which is taken as the minimum of $2K$ and $d - s_i$: in the latter case, this is the last iteration which affects A_i , since it will be known at the wanted precision $d - s_i$.

First, we use fast remaindering to get $R_i = Q(f_i + x^{t_i}y) \text{ rem } A_i$ at precision d in x , simultaneously for all i (see Line 18); this gives us $Q_i \text{ rem } A_i = x^{-s_i}R_i \text{ rem } A_i$ at precision $d - s_i$, and thus $K + \delta_i$. Since A_i is the affine factor of Q_i at precision K , $Q_i \text{ rem } A_i$ is divisible by x^K .

We then look for $A_{i\top} \in \mathcal{S}_{\delta_i}[y]$ such that $\hat{A}_i = A_i + x^K A_{i\top}$ is the affine factor of Q_i at precision $K + \delta_i$; to ensure that \hat{A}_i is still monic, we require that $\deg(A_{i\top}) < \deg(A_i)$. Thus, we can determine $A_{i\top}$

by working modulo A_i : having

$$(A_i + x^K A_{i\top})(B_i + x^K B_{i\top}) = Q_i,$$

at precision $K + \delta_i$, for some $B_{i\top} \in \mathcal{S}_{\delta_i}[y]$, implies that the identity

$$A_{i\top} B_i = x^{-K} Q_i$$

holds modulo A_i and at precision δ_i . Multiplying by $C_i = B_i^{-1}$ on both sides yields

$$A_{i\top} = (x^{-K} Q_i C_i) \text{ rem } A_i = (x^{-K-s_i} R_i C_i) \text{ rem } A_i.$$

Therefore, Line 20 and Line 22 correctly lift the affine factor of Q_i from precision K to precision $K + \delta_i$.

From now on, we work at precision $K + \delta_i$, and, as in the pseudo-code, we denote by A_i the affine factor obtained through the lifting step above (that is, $A_i \leftarrow \hat{A}_i$). Besides, let C_i now denote the cofactor inverse at precision $K + \delta_i$: $C_i = B_i^{-1} \text{ rem } A_i$, where $B_i \in \mathcal{S}_{K+\delta_i}[y]$ is the cofactor such that $Q_i = A_i B_i$. Our goal is to compute C_i , without computing B_i but only $B_i \text{ rem } A_i$.

We remark that the remainder $S_i = Q(f_i + x^{t_i}y) \text{ rem } A_i^2$ (as in Line 24) is such that $x^{-s_i} S_i = Q_i \text{ rem } A_i^2 = A_i (B_i \text{ rem } A_i)$; $x^{-s_i} S_i$ is known at precision $d - s_i \geq K + \delta_i$. Thus,

$$(x^{-s_i} S_i) \text{ quo } A_i = B_i \text{ rem } A_i,$$

and therefore C_i can be obtained as

$$C_i = B_i^{-1} \text{ rem } A_i = ((x^{-s_i} S_i) \text{ quo } A_i)^{-1} \text{ rem } A_i.$$

This shows that Line 26 correctly computes C_i at precision $K + \delta_i$.

PROPOSITION 3.3. *Algorithm 3 is correct and uses*

$$O(d(\deg(Q) + m_1 + \dots + m_\ell))$$

operations in \mathbb{K} .

PROOF. The correctness follows from the above discussion. Concerning the cost bound, we will use the following degree properties. Since A_i is monic, we have the degree bound $\deg(A_i) = \deg(A_i|_{x=0}) \leq m_i$ for all i and at any iteration of the loop; and since C_i is always computed modulo A_i , we also have $\deg(C_i) < m_i$.

The cost of the initialization (Line 1 to Line 11) is dominated by the computation of shifted remainders at Line 2, which costs $O(d(\deg(Q) + m_1 + \dots + m_\ell))$ operations in \mathbb{K} according to Proposition 3.2. The same cost bound holds for each call to ShiftedRem at Line 18 or Line 24, since we have $\deg(A_i) \leq m_i$ and $\deg(A_i^2) \leq 2m_i$.

At both Line 20 and Line 26, the degrees of R_i, C_i , and A_i are at most m_i ; besides, we have $\delta_i \leq d$ and $\delta_i + K \leq 2d$. Thus, the quotient and remainder computations use $O(d(m_1 + \dots + m_\ell))$ operations in \mathbb{K} according to [19, Thm. 9.6].

Finally, at Line 26 we are performing the inversion of the polynomial $((x^{-s_i} R_i) \text{ quo } A_i)$ modulo A_i ; it is invertible in $\mathcal{S}_{\delta_i+K}[y]/(A_i)$ since its x -constant coefficient is a nonzero field element. As a consequence, this inversion can be done in $O((\delta_i + K) \deg(A_i))$ field operations using Newton iteration [19, Thm. 9.4], and altogether Line 26 costs $O(d(m_1 + \dots + m_\ell))$ operations in \mathbb{K} .

Summing these cost bounds over the $\lceil \log_2(d) \rceil$ iterations yields the announced total cost bound. \square

4 FAST SERIES ROOTS ALGORITHM

In this section, we describe our fast algorithm for solving Problem 1. As explained above, it follows the divide and conquer strategy of Algorithm 1, with the main modification being that we incorporate the fast computation of the affine factors of the shifts (Algorithm 3). This leads to a better efficiency by yielding more control on the degrees of the polynomials that are passed as arguments to the recursive calls. Besides, we also propagate in recursive calls the information of the multiplicities of the roots, which is then used as an input of Algorithm 3 to specify the list of degree upper bounds for the affine factors.

We start with a lemma which states that taking affine factors preserves reduced root sets.

LEMMA 4.1. *Let Q be in $\mathbb{K}[[x]][y]$, with $Q|_{x=0} \neq 0$, and let $A \in \mathbb{K}[[x]][y]$ be its affine factor. Then, any reduced root set of A at precision d is a reduced root set of Q at precision d .*

PROOF. The claim follows from the factorization $Q = AB$, with $B|_{x=0} \in \mathbb{K} \setminus \{0\}$. Indeed, as a result, $B(P)$ is a unit in $\mathbb{K}[[x]][y]$ for any P in $\mathbb{K}[[x]][y]$, hence $\mathcal{R}(Q, d) = \mathcal{R}(A, d)$ for any d ; similarly, for any (f, t) , $Q(f + x^t y)$ and $A(f + x^t y)$ have the same valuation, say s , and $Q(f + x^t y)/x^s$ and $A(f + x^t y)/x^s$ differ by a constant factor. In particular, if $\{(f_i, t_i)\}_i$ is a basic root set of A , it is a basic root set of Q , and the multiplicities of (f_i, t_i) in A and Q are the same. This implies that if $\{(f_i, t_i)\}_i$ is in fact a reduced root set of A , it remains so for Q . \square

We continue with a procedure that operates on polynomials in $\mathbb{K}[[x]][y]$, without applying any truncation with respect to x : as such, this is not an algorithm over \mathbb{K} , as it defines objects that are power series in x , but it is straightforward to prove that it outputs a reduced root set. Remark that this procedure uses affine factors at “full precision”, that is, in $\mathbb{K}[[x]][y]$, so Algorithm 3 is not used yet.

Algorithm 4 : SeriesRoots ∞

Input: $d \in \mathbb{Z}_{>0}$ and $Q \in \mathbb{K}[[x]][y]$ such that $Q|_{x=0} \neq 0$.

Output: List of triples $(f_i, t_i, m_i)_{1 \leq i \leq \ell} \subset \mathbb{K}[[x]] \times \mathbb{Z}_{\geq 0} \times \mathbb{Z}_{>0}$ formed by a reduced root set of Q to precision d with multiplicities.

```

1 if  $d = 1$  then
2    $(y_i, m_i)_{1 \leq i \leq \ell} \leftarrow$  roots with multiplicity of  $Q|_{x=0} \in \mathbb{K}[y]$ 
3   return  $(y_i, 1, m_i)_{1 \leq i \leq \ell}$ 
4 else
5    $(f_i, t_i, m_i)_{1 \leq i \leq \ell} \leftarrow \text{SeriesRoots}\infty(Q, \lceil d/2 \rceil)$ 
6    $(s_i)_{1 \leq i \leq \ell} \leftarrow (v_x(Q(f_i + x^{t_i} y)))_{1 \leq i \leq \ell}$ 
7    $(A_i)_{1 \leq i \leq \ell} \leftarrow (\text{AffineFactor}(Q(f_i + x^{t_i} y)/x^{s_i}))_{1 \leq i \leq \ell}$ 
8   for  $1 \leq i \leq \ell$  do
9     if  $s_i \geq d$  then
10       $(f_{i,1}, t_{i,1}, m_{i,1}) \leftarrow (0, 0, m_i)$  and  $\ell_i \leftarrow 1$ 
11    else
12       $(f_{i,j}, t_{i,j}, m_{i,j})_{1 \leq j \leq \ell_i} \leftarrow \text{SeriesRoots}\infty(A_i, d - s_i)$ 
13  return  $(f_i + x^{t_i} f_{i,j}, t_i + t_{i,j}, m_{i,j})_{1 \leq j \leq \ell_i, 1 \leq i \leq \ell}$ .
```

PROPOSITION 4.2. *Algorithm 4 is correct.*

PROOF. We prove this by induction on $d \geq 1$. By Lemma 2.7, the algorithm is correct for the induction base case $d = 1$. Take $d > 1$,

and assume that the algorithm is correct for all $d' < d$. Then, we obtain a reduced root set (f_i, t_i) from the first recursive call, so in particular the valuations s_i are at least equal to $d' \geq 1$. This shows that $d - s_i < d$, so the second recursive call is made at a lower precision, and the procedure terminates.

By induction, in all cases, $(f_{i,j}, t_{i,j})_{1 \leq j \leq \ell_i}$ is a reduced root set of Q_i to precision $d - s_i$: this is obvious when $s_i \geq d$, and follows from Lemma 4.1 when $s_i < d$. Theorem 2.8 implies that $(f_i + x^{t_i} f_{i,j}, t_i + t_{i,j})_{1 \leq j \leq \ell_i, 1 \leq i \leq \ell}$ is a reduced root set of Q to precision d . We verify that the integers $m_{i,j}$ are the associated multiplicities as we did in the proof of that theorem. \square

Next, we describe a similar algorithm, where we maintain the input polynomial with degree less than d in x (when it is the case, we say that it is *reduced modulo x^d*). To differentiate this version from the previous one and facilitate proving the correctness, we add a superscript $*$ to the objects handled here when they differ from their counterpart in Algorithm 4. Remark that we do not claim that the output forms a reduced root set of Q^* , merely a basic root set; we also do not claim that the m_i 's in the output are the corresponding multiplicities.

Algorithm 5 : SeriesRootsTrc

Input: $d \in \mathbb{Z}_{>0}$ and $Q^* \in \mathbb{K}[[x]][y]$ reduced modulo x^d such that $Q^*|_{x=0} \neq 0$.

Output: List of triples $(f_i, t_i, m_i)_{1 \leq i \leq \ell} \subset \mathbb{K}[[x]] \times \mathbb{Z}_{\geq 0} \times \mathbb{Z}_{>0}$ formed by a basic root set of Q^* to precision d .

```

1 if  $d = 1$  then
2    $(y_i, m_i)_{1 \leq i \leq \ell} \leftarrow$  roots with multiplicity of  $Q^*|_{x=0} \in \mathbb{K}[y]$ 
3   return  $(y_i, 1, m_i)_{1 \leq i \leq \ell}$ 
4 else
5    $(f_i, t_i, m_i)_{1 \leq i \leq \ell} \leftarrow \text{SeriesRootsTrc}(Q^* \bmod x^{\lceil d/2 \rceil}, \lceil d/2 \rceil)$ 
6    $(A_i^*, s_i^*)_{1 \leq i \leq \ell} \leftarrow \text{AffineFacOfShifts}(Q^*, d, (f_i, t_i, m_i)_{1 \leq i \leq \ell})$ 
7   for  $1 \leq i \leq \ell$  do
8     if  $s_i^* = d$  then
9        $(f_{i,1}, t_{i,1}, m_{i,1}) \leftarrow (0, 0, m_i)$  and  $\ell_i \leftarrow 1$ 
10    else
11       $(f_{i,j}, t_{i,j}, m_{i,j})_{1 \leq j \leq \ell_i} \leftarrow \text{SeriesRootsTrc}(A_i^*, d - s_i^*)$ 
12  return  $(f_i + x^{t_i} f_{i,j}, t_i + t_{i,j}, m_{i,j})_{1 \leq j \leq \ell_i, 1 \leq i \leq \ell}$ .
```

PROPOSITION 4.3. *Algorithm 5 is correct.*

PROOF. We claim that for $d > 0$ and any Q and Q^* in $\mathbb{K}[[x]][y]$ such that $Q^* = Q \bmod x^d$, the outputs of $\text{SeriesRoots}\infty(Q, d)$ and $\text{SeriesRootsTrc}(Q^*, d)$ are the same. Before proving this claim, remark that it implies the correctness of Algorithm 5: we know that this output is a reduced, and thus basic, root set of Q to precision d . Since Q and Q^* are equal modulo x^d , one verifies easily that this output is thus a basic root set of Q^* to precision d as well.

We prove the claim by induction on d . If $d = 1$, the result is clear, as we compute the same thing on both sides.

For $d > 1$, since $Q^* \bmod x^{\lceil d/2 \rceil} = Q \bmod x^{\lceil d/2 \rceil}$, the induction assumption shows that $(f_i, t_i, m_i)_{1 \leq i \leq \ell}$ as computed in either $\text{SeriesRoots}\infty$ or SeriesRootsTrc are the same.

The affine factors of the shifts of Q and Q^* differ, but they coincide at the precision we need. Indeed, the equality $Q = Q^* \bmod x^d$ implies that for all i , $Q(f_i + x^{t_i}y) = Q^*(f_i + x^{t_i}y) \bmod x^d$. In particular, if $s_i < d$, these two polynomials have the same valuation s_i , and $Q(f_i + x^{t_i}y)/x^{s_i} = Q^*(f_i + x^{t_i}y)/x^{s_i} \bmod x^{d-s_i}$, which implies that their affine factors are the same modulo x^{d-s_i} . If $s_i \geq d$, then $Q^*(f_i + x^{t_i}y)$ vanishes modulo x^d .

Remark that the assumption of Algorithm 3 is satisfied: for all i , m_i is the multiplicity of (f_i, t_i) in Q ; the definition of a reduced root set then implies that $\deg(Q|_{x=0}) \leq m_i$, so that the same degree bounds holds for the affine factors of $Q^*(f_i + x^{t_i}y)/x^{s_i}$. As a result, for i such that $s_i \geq d$, Algorithm 3 returns $(0, s_i^*) = (0, d)$, whereas if $s_i < d$, it returns (A_i^*, s_i) , where A_i^* is the truncation modulo x^{d-s_i} of the affine factor A_i of Q_i . In the first case, the polynomials $(f_{i,1}, t_{i,1}, m_{i,1})$ are the same in both algorithms; in the second case, this is also true, by induction assumption. Our claim follows. \square

PROOF OF THEOREM 1.2. To conclude the proof of Theorem 1.2, it remains to estimate the cost of Algorithm 5. Let $T(n, d)$ denote the cost of Algorithm 5 on input d and Q of degree $n = \deg(Q)$. If $d = 1$, then $T(n, 1) = R_{\mathbb{K}}(n)$. Otherwise, the cost is given by the following recursion:

$$T(n, d) = T(n, d/2) + S(n, d, (n_1, \dots, n_\ell)) + \sum_{i=1}^{\ell} T(n_i, d - s_i),$$

where $S(n, d, (n_1, \dots, n_\ell))$ is the cost of AffineFactorsOfShifts and $n_i = \deg(A_i^*)$. The degrees of the polynomials A_i^* , in Algorithm 5, and A_i , in Algorithm 4, are the same, except for those cases where $s_i \geq d$ and A_i^* is actually zero. By definition of a reduced root set, we have

$$\sum_i \deg(A_i) \leq \deg(Q|_{x=0}) \leq n,$$

which thus implies $\sum_i n_i \leq n$, and $S(n, d, (n_1, \dots, n_\ell)) \in O(dn)$. Note also that $s_i \geq d/2$ by the correctness of SeriesRootsTrc. Since $T(n, d)$ is at least linear in n , we then get $\sum_i T(n_i, d - s_i) \leq T(n, d/2)$. This gives the upper bound

$$T(n, d) \leq 2T(n, d/2) + O(nd),$$

from which we deduce that $T(n, d) = O(nd) + O(dR_{\mathbb{K}}(n))$. \square

Finally, we point out an optimization, which is not necessary to establish our main result, but useful in practice: once the affine factor of a shift has degree 1, there is no need to continue the recursion (the affine factor being monic, we can just read off its root from its constant coefficient). This is the analogue of the situation described in the introduction, when we know enough terms of the solution to make it possible to apply Newton iteration without further branching.
